"Simulation has been used on a continuous basis at Swan Wooster as a valuable tool in planning and design of projects since the late 1960s. The simulation concept has been applied to railway costing in order to assist in rail tariff negotiations between shippers and carriers of various types; to analyze mine to overseas consumer total transportation systems; to analyze in detail the materials handling systems of a number of complex terminals, and to help design railway terminal yards. The simulation approach is also being extended into operational simulations, linked to automatic control of operating terminals, to assist management make day-to-day operating decisions. The processes of design and simulation have been interlinked. A cycle procedure is now used to converge upon the final recommended design. A particular design is recommended, then tested by simulation, then evaluated for performance, and then revised as necessary. The cycle of testing, evaluation and revision is continued until a satisfactory design is achieved. A number of major clients now consider simulation and its possibilities for unified design planning to be an essential first step before proceeding into more detailed design. These clients have recognized that simulation makes it possible to examine the interdependencies of a transportation system simultaneously to ensure that all parts are in harmony with the whole. They feel that this approach is superior to the conventional design process in which various components are designed separately, with little concern for their impact on other parts of the system"--Page [2].

Understanding the dynamics of railway vehicles, and indeed of the entire vehicle-track system, is critical to ensuring safe and economical operation of modern railways. As the challenges of higher speed and higher loads with very high levels of safety require ever more innovative engineering solutions, better understanding of the technical issues a
